

XML import

4PSA DNS Manager allows the administrator to import an XML file that is a backup of the database.

An administrator account is able to import administrators, clients and zone accounts and also global server settings from the XML file. The details of the existing administrators' and clients' account will be updated.

The accounts are identified through the login username. When a new account is created using the import XML method, an email will be sent to the address found in the XML file (in the Account Details section) sending the new password to the new created user. The existing client's account details will be updated.

From the XML file, new zones are created. The records from existing zones are replaced with the records from the XML file. Zones that do not have any records will not be created.

The zones that are defined on the server will not be deleted if they do not exist in the XML file.

To import a database in XML format, the administrator must click the **XML import** button in the Database section of the **Server Settings** page. Then use the **Browse** button to locate the backup file.
